Ecological Site Description

Shallow Sandstone Upland Glade/Woodland  
(R112XY033MO)

- (Quercus marilandica/Rhus copallina/Schizachyrium scoparium - Crotonopsis elliptica)
- (blackjack oak/winged sumac/little bluestem – Michaux’s croton)

An Ecological Site Description (ESD) is a reference document of ecological knowledge regarding a particular land area (ecological site). An ESD describes ecological potential and ecosystem dynamics of land areas and their potential management. Ecological sites are linked to soil survey map unit components, which allows for mapping of ecological sites. *(NOTE: This is a “provisional” ESD, and is subject to change. It contains basic ecological information sufficient for conservation planning and land management in Missouri. After additional information is developed and reviewed, a “Correlated” ESD will be published and will be available via the Web Soil Survey http://websoilsurvey.nrcs.usda.gov.)*

Major Land Resource Area: 112 – Cherokee Prairies

Introduction

The Cherokee Prairies (area outlined in red on the map) is a nearly level to rolling, weakly dissected plain. Elevation ranges from about 330 feet along the Verdigris River in the south to over 1,300 feet along the northwest border with the Flint Hills. Local relief is three to ten feet, with major valley floodplains typically less than eight feet below the adjacent uplands. The northern and eastern part of the area is primarily in the Osage River watershed, and the southern part is mainly in the Neosho and Verdigris River watersheds. Loess blankets the northern part of the area but thins to the south. Nearly all of the upland plain is underlain with Pennsylvanian aged sandstones and shales, and most upland soils are formed in residuum from these materials.

Shallow Sandstone Upland Glade/Woodlands are within the green areas on the map (Missouri portion only; relationships to Kansas and Oklahoma Ecological Sites are currently under review). These sites are primarily on slopes above the Osage River and tributaries in St. Clair, Vernon and Barton counties, Missouri. They are often associated with Shallow Sandstone Backslope ecological sites. Soils are shallow to sandstone bedrock.

Physiographic Features

This site is on upland shoulders and backslopes with slopes of 2 to 20%. The site generates runoff to adjacent, downslope ecological sites, and in places receives runoff from upslope summit and shoulder sites. This site does not flood.

Soil Features

These soils are underlain with sandstone bedrock at less than 20 inches. The soils were formed under woodland vegetation, and have thin, light-colored surface horizons. Parent material is
sandstone residuum. These soils are loamy, with high amounts of sandstone fragments. They are not affected by seasonal wetness. Soil series associated with this site include Hector.

**Ecological Dynamics**

*Information contained in this section was developed using historical data, professional experience, field reviews, and scientific studies. The information presented is representative of very complex vegetational communities. Not all scenarios or plants are included. Key indicator plants, animals and ecological processes are described to help inform land management decisions.*

Shallow Sandstone Upland Glade/Woodlands harbor a wide diversity of lichens, plants and animals. The dominant grasses include little bluestem, broomsedge and Indian grass. The glade/woodland complexes range from wide open grassy areas with very shallow soils and bare bedrock, to areas with widely scattered blackjack oaks on slightly deeper soils. They are most frequently found on gentle slopes facing stream valleys where they are imbedded in a matrix of sandstone/shale prairies and woodlands. Federally listed *Geocarpon minimum* is known only from these glades in Missouri. While most have suffered from grazing and fire suppression, good examples can still be found.

The shallow soils of the Shallow Sandstone Upland Glade/Woodlands limit the growth and abundance of trees and support the native grasses and forbs that dominate these systems. Trees found on and near glades are often stunted and express poor development because of shallow droughty soils and poor growing conditions. Like the adjacent prairies, fire also played an important role in the maintenance of these systems. These systems typically burned at least once every three years. These periodic fires removed the litter and stimulated the growth and flowering of the grasses and forbs. They also further limited the growth and dominance of trees. Fire tolerant blackjack oak occupied islands and edges of deeper soils, creating a complex mosaic of open glade and low-density woodland.

These are low productive sites. During fire-free intervals, woody species increased, especially on protected slopes. Once established, blackjack oak, Eastern redcedar and sumac can quickly fill in a glade/woodland system, especially if grazing has diminished the vigor of the diverse flora. Many glades have been heavily grazed and suffer substantial woody invasion. Removal of the woodies and the application of prescribed fire have proven to be effective management tools.

Site Interpretations

**Wildlife Species**

- Wildlife habitat: oaks provide hard mast; numerous native legumes provide high-quality wildlife food; native warm-season grasses provide extensive cover and nesting habitat; and a diversity of forbs provides a diversity and abundance of insects. Post-burn areas can provide temporary bare-ground – herbaceous cover habitat important for turkey pouls and quail chicks.

- Game species that utilize this ecological site include:
  Northern Bobwhite will utilize this ecological site for food (seeds, insects), cover needs (escape, nesting and roosting cover) and brood-rearing habitat.

  Cottontail rabbits will utilize this ecological site for food (seeds, soft mast) and cover needs.
Turkey will utilize this ecological site for food (seeds, green browse, soft mast, and insects) and nesting and brood-rearing cover. Turkey poult feed heavily on insects provided by this site type.

White-tailed Deer will utilize this ecological site for browse (plant leaves in the growing season, seeds and soft mast in the fall/winter). This site type also can provide escape cover.

- Bird species associated with this ecological site’s reference state condition:

- Amphibian and reptile species that may be associated with this ecological site’s reference state: Five-lined Skink (*Eumeces fasciatus*), Six-lined Racerunner (*Cnemidophorus sexlineatus*), Flat-headed Snake (*Tantilla gracilis*), Eastern Coachwhip (*Masticophis flagellum flagellum*), Red Milk Snake (*Lampropeltis triangulum syepila*), Ground Snake (*Snora semiannulata*) and Prairie Ring-necked Snake (*Diadophis punctatus arnyi*).

- Small mammals likely associated with this ecological site’s reference state condition: Eastern Woodrat (*Neotoma floridana*) and *Peromyscus* species.

- Invertebrates – Many native insect species are likely associated with this phase of this ecological site’s reference state condition, especially native bees, ants, beetles, butterflies and moths, and crickets, grasshoppers and katydids.

- Insect species likely associated with this ecological site’s reference state condition: Lichen Grasshopper (*Trimerotropis saxatilis*), a prickly pear borer moth (*Melitara prodenialis*), native ants (*Pheidole tysoni, Formica schaufussi*), and native bees (*Colletes aestivalis, Andrena helianthiformis, Protandrena rudbeckiae, Lasioglossum coreopsis, Anthidium psoraleae and Dianthidium subrubrum*)

**Glossary**

*Alfic* – soil that has a clay-dominated subsoil (argillic horizon) with moderate to high amounts of bases such as calcium, and were typically formed under woody vegetation.

*Backslope* – a hillslope profile position that forms the steepest and generally linear, middle portion of the slope.

*Backswamp* – marshy or swampy, depressed areas of flood plains between natural levees and valley sides or terraces.

*Calcareous* – the presence of calcium carbonate in the soil parent material within the rooting zone; relatively alkaline.

*Claypan* – a dense, compact, slowly permeable layer in the subsoil having much higher clay content than the overlying material.
Chert – hard, extremely dense or compact crystalline sedimentary rock, consisting dominantly of interlocking crystals of quartz

Cliff – a significant vertical, or near vertical, rock exposure

Dolomite – a type of sedimentary rock that is a carbonate mineral composed of calcium magnesium carbonate

Drainageway – the upper most reach of a stream channel system characterized by little meandering

Dry – a site where soil moisture is limiting during the growing season; low available water capacity

Dune – a low mound, ridge, bank or hill of loose, wind-blown sand

Exposed – steep, south and west-facing slopes, which are warmer and drier than other slope aspects

Flatwoods – a type of woodland that occurs on soils with a root restricting subsoil layer within 20 to 30 inches, resulting in very slow runoff and ponding that remains saturated for most of the winter and early spring months but dries out and becomes very dry in the summer months; plants that grow there must be adapted to both conditions

Floodplain – the nearly level plain that borders a stream and is subject to inundation under flood-stage conditions

Foothslope – a hillslope position at the base of a slope where hillslope sediment (colluvium) accumulates

Forest – a vegetative community dominated by trees forming a closed canopy and interspersed with shade-tolerant understory species

Fragipan – a dense, brittle subsoil horizon that is extremely hard and compact when dry

Glade – open, rocky, barren vegetative community dominated by drought-adapted forbs and grasses, typically with scattered, stunted woody plants

Igneous – bedrock formed by cooling and solidification of magma. Granite and rhyolite are typical igneous bedrocks in Missouri

Limestone – a type of sedimentary rock composed largely of calcium carbonate

Loess – material transported and deposited by wind and consisting predominantly of silt-size particles

Loamy – soil material containing a relatively equal mixture of sand and silt and a somewhat smaller proportion of clay

Marsh – a type of wetland that is dominated by herbaceous rather than woody plant species

Moist – a site that is moderately well to well drained and has high available water capacity, resulting in a well-balanced supply of moisture (neither too dry nor too wet).

Molllic – soil that has a thick, dark surface horizon and was typically formed under prairie vegetation
**Mudstone** – blocky or massive, fine-grained sedimentary rock in which the proportions of clay and silt are approximately equal

**Natric** – a soil horizon that displays a blocky, columnar, or prismatic structure and has a subhorizon with an exchangeable-sodium saturation of over 15%

**Outwash** – stratified sediments of sand and gravel removed or “washed out” from a glacier by melt-water streams

**Pinery** – a vegetative community within the historic pine range in Missouri that has shortleaf pine as a significant tree species

**Prairie** – a vegetative community dominated by perennial grasses and forbs with scattered shrubs and very few trees

**Protected** – steep, north- and east-facing slopes, which are cooler and moister than other slope aspects

**Residuum** - unconsolidated, weathered, or partly weathered mineral material that accumulates by disintegration of bedrock in place

**Riser** – a component of terraces and flood-plain steps consisting of the steep side slope; the escarpment

**Riverfront** – a vegetative community in the floodplain immediately adjacent and generally parallel to a river or stream channel

**River hills** – a geographic area characterized by thick, dissected loess deposits, formed immediately adjacent to the edges of the Missouri and Mississippi River floodplains

**Sandy** – a coarse-sized soil containing a large mixture of sand and gravels and a somewhat smaller proportion of silts and clays with excessive drainage

**Sandstone** – a sedimentary rock containing dominantly sand-size particles

**Savanna** – grasslands interspersed with open-grown scattered trees, groupings of trees, and shrubs

**Shale** – a sedimentary rock formed from clay, silty clay, or silty clay loam deposits and having the tendency to split into thin layers

**Shallow** – a site with bedrock within 20 inches of the surface

**Shoulder** – the slope profile position that forms the convex surface near the top of a hill slope; it comprises the transition zone from summit to backslope

**Sinkhole** – a closed, circular or elliptical depression, commonly funnel-shaped, characterized by subsurface drainage and formed either by dissolution of the surface of underlying bedrock or by collapse of underlying caves within bedrock

**Summit** – the top or highest area of a hillslope

**Swale** – shallow, closed depressions irregularly spaced across a floodplain or terrace with an irregularly undulating surface.
**Swamp** – an area of low, saturated ground, intermittently or permanently covered with water, and predominantly vegetated by shrubs and trees.

**Talus** – rock fragments of any size or shape (usually coarse and angular) derived from and lying at the base of a cliff or very steep rock slope.

**Terrace** – a step-like surface, bordering a valley floor that represents the former position of a flood plain

**Till** – dominantly unsorted and unstratified soil material deposited directly by a glacier

**Ultic** – soil that has a clay-dominated subsoil (argillic horizon) with low amounts of bases such as calcium, and were typically formed under woody vegetation

**Upland** – a general term for the higher ground of a region, in contrast with a low-lying, adjacent land such as a valley or floodplain

**Wet** – a somewhat poorly, poorly or very poorly drained site that has an oversupply of moisture during the growing season

**Woodland** – a highly variable vegetative community with a canopy of trees ranging from 30 to 100 percent closure with a sparse midstory and a dense ground flora of grasses, sedges and forbs
