NATURAL RESOURCES CONSERVATION SERVICE
CONSERVATION PRACTICE STANDARD
LIVESTOCK SHELTER STRUCTURE
(No.)
CODE 576

DEFINITION
A permanent or portable structure with less than four walls and/or a roof to provide for improved utilization of pastureland and rangeland and to shelter livestock from negative environmental factors. This structure is not to be construed to be a building.

PURPOSE
• To provide protection for livestock from excessive heat, wind, cold, or snow.
• Protect surface waters from nutrient and pathogen loading.
• Protect wooded areas from accelerated erosion and excessive nutrient deposition by providing alternative livestock shelter/shade location.
• Improve the distribution of grazing livestock to enhance wildlife habitat, reduce over-used areas, or correct other resource concerns resulting from improper livestock distribution.

CONDITIONS WHERE PRACTICE APPLIES
This practice is applied to provide protection to sensitive areas by providing a source of shade or shelter that is located away from the existing shade or shelter in wooded areas or on stream banks or depressions. This practice must be used in conjunction with exclusion of animals from the sensitive area. Use a livestock exclusion practice NRCS Conservation Practice Standard (CPS) Fence (382).

This practice is applicable where animal productivity and well-being are adversely affected by negative environmental conditions such as direct and unimpeded sunshine, wind, or snow.

This practice can facilitate livestock management under prescribed grazing to protect water quality and soil health.

This practice can be used to provide protection on range or pasture; cropland or hayland used for grazing; winter feeding areas; or in a livestock heavy use area.

CRITERIA
General Criteria Applicable to All Purposes and Structure Types
Structures. Design any structures associated with livestock shelters including roofs, according to appropriate NRCS standards. Where NRCS standards do not exist, design structures according to the requirements of the particular construction material and accepted engineering practice. Base environmental design loads on criteria in SEI/ASCE 7 - Minimum Design Loads for Buildings and Other Structures.
Transport of Portable Structure. Equip the portable structure with runners or wheels or other means to facilitate transport. Provide lateral support to vertical and horizontal structural members to prevent twisting and/or buckling.

Location. Locate the structure to avoid adverse effects to cultural resources and endangered, threatened, and candidate species and their habitat. Select upland locations that are away from riparian areas and concentrated flow areas to avoid impairment of water quality. Locate structures a minimum of 100 feet from any surface water bodies, 150 feet from an up-gradient well and 300 feet from a down-gradient well. Select location(s) that will not have surface water flow through the structure. Livestock shelter structures should be located considering appropriate access and travel distance to watering facilities for the livestock. Appropriate watering facilities for the planned season(s) of use should be considered when locating shelter structures.

Erosion Protection. Provide erosion protection from roof runoff. Where appropriate, stabilize all areas disturbed by construction with vegetation as soon as possible after construction. Refer to NRCS CPS Critical Area Planting (342). If vegetation is not appropriate for the site, use CPS Heavy Use Area Protection (561) to stabilize the area.

Materials. Construct the structure of durable materials that are commensurate with a minimum structure life of 10 years. Fabric or other non-structural material may need to be replaced in accordance with its anticipated lifespan (typically no more than 5 years). Dispose of or recycle worn out fabric or other non-structural material as appropriate.

Waste Management. Design the structure to facilitate the distribution of manure across grazing lands in accordance with the grazing management plan or a nutrient management plan, as appropriate for the particular site.

Prescribed Grazing. When the livestock protection structure is installed to improve livestock distribution to address resource concerns, then NRCS CPS Prescribed Grazing (528) must also be included in the resource management plan.

Additional Criteria Applicable to Shade Structures
Orientation. Orient the longest axis in a north to south direction to maximize the amount of shade and to allow sunlight to dry the area under the structure.

Shade cover. Design the top of the structure to be relatively flat so that wind will have minimum load on the structural supports. Provide a minimum1:25 pitch for the structure roof to allow runoff. Anchor the four corners of the shade structure with tie-downs of adequate size and strength to meet the local wind conditions during season of use.

Size. The minimum size requirements for a shade structure are shown in Table 1. Limit the maximum size of individual shade structure units to 25 feet wide by 50 feet in length (1250 sq ft). Portable structures may be smaller to facilitate movement. Multiple structures may be needed depending on the number of animals to be sheltered.

In prescribed grazing systems for high-producing livestock, provide shade for at least 75% of the herd, particularly for dairy or beef cows.
Table 1 – Minimum Shade Requirements

**Location.** Locate the structure a minimum of 50 feet from any existing structure that could obstruct the circulation of air. Use the location of the structure to create the desired livestock travel patterns. Move portable structures as needed to maintain healthy vegetation in the immediate area.

**Additional Criteria Applicable to Wind Shelter Structures**

**Location.** Locate the wind shelter structure in an area where livestock shelter from prevailing winds is desired. See Figure 2. The site must be accessible by vehicle or equipment. Locate the fabricated windbreak on uplands away from riparian areas and concentrated flow areas so any waste concentration will no longer impair water quality.

**Figure 2 – Typical Wind Shelter Structures**

Locate the shelter on level, uninterrupted terrain, if possible. If the shelter must be located downwind of a hill, place the shelter as far downwind as possible. A shelter upwind of a hill shall be placed a minimum of 75 times the shelter height upwind of the base of the hill.

Locate wind shelters perpendicular to the prevailing wind for the planned season of use for the shelter. Determine the prevailing wind direction by using Wind Rose from the South Dakota State University Climate and Weather website [https://climate.sdstate.edu/tools/windrose/windrose.shtm](https://climate.sdstate.edu/tools/windrose/windrose.shtm). Be careful that wind shelters do not block summer breezes, increasing heat stress.

**Shape and Size.** Wind shelters shall be a 90° “V” shaped, semi-circular shaped, or straight line structures.

For optimum protection from wind and drifting snow, a “V” shaped or semicircular structure is recommended. The shelter opening width (perpendicular to the wind direction) should be no wider than 15 times the shelter height.

**“V” Shelters.** Construct “V” shaped shelters with a solid face to divert drifting snow around ends of the barrier. Wind speed reduction of 60-80 percent is possible in the protected area extending 5H downwind of the barrier (Figure 3). The V, or closed end, should point in the direction of the winter and early spring
prevailing winds. The shelters cause the snow to be diverted around the shelter and deposited in drifts extending five times the shelter width (D) downwind.

A minimum length is needed to protect from eddy currents (whirlwinds) at shelter ends, however if the shelter is too long, drifting snow is forced up, over the shelter into the protected area rather than being diverted around it. Generally, the length of each wing of the shelter should be 7-10 times the shelter height.

Compute the shelter zone area as shown in Figure 3. Table 2 shows the shelter zone. The shelter structure shall provide a shelter zone area based on the values in Table 2.

Design the shelter dimensions following guidance provided in Tables 2 and 3.

Semi-circular Shelters. Semi-circular shaped shelters can be built with approximately the same quantity of materials as the “V” design. The ratio of protected area to shelter length is about 27 percent higher than in the “V” shape. Base the dimensions for the semi-circular shaped barrier on a radius equal to one-half D for the “V” shaped barriers as shown in Table 3. Semi-circular shelters are generally the most economical (material cost per square foot); however, the type of material used for board or panels can be a limiting factor due to the shape. The semi-circular shape also tends to be self-bracing.

Straight line shelters. Straight line windbreaks are not as effective as the “V” shaped design since less protection is provided if wind direction varies from anything perpendicular to the fence. They will however provide effective wind protection for up to 15 to 20 times the height of the structure for solid and porous walls. Snow is forced over the fence and deposited downwind of the structure rather than diverted around it. Fence shelters may be designed either as solid barriers or as porous (open) fences. Solid fences are typically located adjacent to the lot to be protected along the lot perimeter since snow accumulation does not usually extend out far from the fence. Wind protection is good in the area next to the fence. Wind drops the snow upwind of the fence a distance of 1 fence height (1H) and downwind of the fence 5H. The wind protection area extends 15H downwind of the fence (10H below the snow drop zone). See Figure C.

Porous or open fences are more effective at controlling wind than solid fences and drop more snow. The porous fences are usually located upwind of the lot far enough to keep the area to be protected out of the snow drop zone. The major snow drop zone is of shallower depth than a solid fence but extends downwind a greater distance (10H) from the barrier. The wind protection area extends 20H downwind of the fence (10H below the snow drop zone). See Figure D.

Porous barriers must have approximately 80 percent solid and 20 percent open surface area (Figure B). The openings may run vertically or horizontally. Porous barriers must be mounted approximately 12 inches above the ground to reduce eddy currents (whirlwinds) and allow wind to keep sweeping the snow downwind of the fence.

General Structural Criteria. Post spacing and depth will require site specific designs based on sustained wind speed and direction, or sizes and spacing shown in Table 4 may be used.

Lumber installed within eight inches of the ground must be pressure treated in accordance with ASTM D1760 Standard Specification for Pressure Treatment of Timber products. For facilities that are organic producers or that sell compost to organic producers, ensure that the treated lumber used in the shelter meets the requirements for organic production. It may be best to have the producer consult with the organic certifier as to the use and acceptability of treated lumber.

Use a minimum nominal 1-inch lumber, 22-gauge coated corrugated steel, or similar durability materials as a panel covering. Provide rub rails or other features to protect the structure from animal damage. Place rub rails on the downwind side of the shelter. Use 2” x 10” pressure treated wood planks, galvanized metal guard rail, drill stem pipe, or other approved materials to construct rub rails.

CONSIDERATIONS

Permanent structures should be centrally located in the grazing system to promote equidistant travel to all grazing areas.

The livestock shelter structure may require pollution and erosion prevention measures in the design.

Consider the economics, the overall waste management system plan, and safety and health factors.

If the structure is permanent, consider applying NRCS Conservation Practice Standard Heavy Use Area Protection (561) where vegetation cannot be maintained underneath or within the structure.

When applicable, consider the use of NRCS Conservation Practice Standard Trails and Walkways (575) when frequent travel to headquarters, grazing areas or watering facilities is required.

With portable shade structures, consider removing and storing the structure or fabric during winter months to extend the life of the shade cloth.

Consider removing and storing mobile shade structures during stormy weather events.

Consider soil types and seasonal water table zones when planning the location of the livestock shelter structure.

PLANS AND SPECIFICATIONS

Prepare plans and specifications for a livestock shelter structure according to this standard. Describe the requirements for applying the practice to achieve its intended purposes.

Include construction plans, drawings, job sheets or other similar documents. Specify in these documents the requirements for installing the practice.

As a minimum, include:

- The type, location (if permanent structure), and orientation of the shelter structure.
• Wind calculations, as needed to set minimum thicknesses, strengths, etc., for the structures based on a standard design wind speed. Include the seasonal wind directions needed to determine the orientation of the structure.
• Develop a plan for movement of the structure, if portable.
• Job sheets or construction drawings.
• Construction specifications including dimensions of the structure, and configuration.
• Materials, including the dimensions, amount, any coatings, and quality to be used.

OPERATION AND MAINTENANCE
An operation and maintenance (O&M) plan shall be prepared for and reviewed with the owner/operator.

The minimum requirements to be addressed in the O&M plan are:
• Inspect the structure annually and after major storm events.
• Maintain the structural and fabric components through the practice lifespan.
• Replace and/or repair maintenance coatings on structural steel components as necessary.
• Periodically tighten the shade cloth to minimize wind damage.
• Replace the fabric cover when it has deteriorated due to environmental conditions.
• Move portable structures periodically to prevent destruction of vegetation in the immediate area.
• If shelters are not moved frequently, collect and remove accumulated animal waste on a regular basis or specified time interval and utilize in accordance with NRCS CPS Waste Recycling (633) or Nutrient Management (590), as appropriate.
