

The attached tables are to be used to determine the appropriate Soil Erodibility category to be used for the design of conservation practices in Nebraska. While most commonly used in the design of grassed waterways, these erosion categories are to be used to design any practices that result in flow within an earthen channel. These practices may include terraces, diversions, open channels, etc.

The erosion categories should also be used as appropriate for design of components within a practice such as auxiliary spillways for ponds.

All soil map units are grouped in to one of four erodibility categories. Each category will have a limiting (non-erosive) velocity to be used for design. The table below represents the erosion category and the corresponding limiting velocity.

Erodibility Category	Non-Erosive Velocity (ft/s)
Easily Eroded	1.5
Erodible	2.0
Erosion Resistant	2.5
Very Erosion Resistant	2.8

It should be noted that the velocities listed are general values. Maximum velocities in the table should only be used if specific velocities are not included in the practice standard for the practice being designed.

The velocities listed are for cultivated (bare) earth conditions. Design velocities may be increased if appropriate measures, such as vegetation or other techniques of armoring the channel, are taken to protect against erosion. Sound engineering judgment must be used when higher velocities are anticipated.

Soil Erodibility Category Analysis

The Erodibility Category Analysis is based on Research conducted by the Agricultural Research Service and NRCS in Iowa. The following is the procedure used:

1. The soil survey data base gives a range of plasticity indexes (PI) for each soil type. It also gives a value that is generally an average of the high and low value, but in some cases may not be the arithmetic average. It is shown as the $PI_{r \text{ value}}$. This is the number that was used to determine the allowable soil stress.
2. For soils with a plasticity index equal to or greater than 10, the formulas in appendix B of EFH, Chapter 7, Waterways was used to determine the allowable soil stress. The formulas vary depending on the unified soil classification type.
3. For soils that had PI's that were not in the above range, the following criteria was used:
 - a. For ML soils with $5 \leq PI < 10$ \Rightarrow Erodible
 - b. For ML soils with $PI < 5$ \Rightarrow Easily Eroded
 - c. For SC soils with $5 \leq PI < 10$ \Rightarrow Erodible
 - d. For SC soils with $PI < 5$ \Rightarrow Easily Eroded
 - e. For CL soils with $PI < 10$ \Rightarrow Erosion Resistant
 - f. For SM soils with $PI < 10$ \Rightarrow Easily Eroded

The soils information (unified soil classification and plasticity indexes) was obtained from NASIS (National Soil Information System).

Tables were developed which showed the soil erodibility category for each soil type. These were sent to the Area Engineers for their review. It is the intent to make the soil erodibility category tables somewhat dynamic as we expect some suggestions for changes to come from the field once the tables and Waterway Design Tool are fully implemented.

SOIL ERODIBILITY CATEGORY FOR NEBRASKA SOILS

Soil #	Soil Name	Erodibility Category
